SAP® OpenUI5 for Mobile BI and Analytics

- ▶ Delve into the foundations of CSS, HTML5, and jQuery
- ▶ Use open source library d3.js to create custom data visualizations for bar, line, and pie charts
- ▶ Learn how to build a seamless mobile BI app using SAP OpenUI5
- ▶ Build web apps using real world scenarios and test layout options for different mobile devices

Table of Contents

Preface	9
Personal dedication	9
1 Introduction to SAP OpenUI5 for Mobile BI	11
1.1 Mobile BI software	12
1.2 HTML5 to bridge the gap	14
1.3 Chapter overview	14
2 Mobility and BI	19
2.1 The evolution of mobile devices	20
2.2 The big data explosion	22
2.3 Real-time access to information	24
2.4 The death of Adobe Flash?	27
2.5 Culture and BI maturity	28
3 Design Thinking	33
3.1 Information architecture	35
3.2 Use case scenarios	37
3.3 Summary	51
4 HTML5 for any screen size, browser and device	53
4.1 The age-old browser compatibility issue	54
4.2 Android, iOS, Blackberry and Windows	55
4.3 Wearables and IoT	56
4.4 Screen resolution and touchscreen interfaces	56
4.5 Agile and rapid application development (RAD)	60
4.6 Native vs. browser-based apps	62
4.7 Overview of jQuery Mobile	66
4.8 SAP OpenUI5 Introduction	76

5	Building the HTML5 Skeleton	79
5.1	Web standards	79
5.2	HTML basics	82
5.3	New to HTML5	100
5.4	Formatting and styling with CSS	104
5.5	Layout options	113
5.6	Going offline	115
6	SAP OpenUI5 Stack	117
6.1	Getting started with OpenUI5	117
6.2	Overview of the OpenUI5 stack	121
6.3	Full screen vs. split screen	184
7	Graphs, Charts and Maps	187
7.1	Design guidelines and data visualization tips	187
7.2	Open source charts and graphs	195
7.3	Adding graphs and charts to our web app	200
7.4	APIs: geo-location and Google Maps	222
8	Displaying data from multiple sources	227
8.1	Relational vs. NoSQL	227
8.2	A look at server-side scripting	230
8.3	Connecting to Oracle, MySQL	233
8.4	OData application	240
8.5	Overview of IndexedDB API	245
9	Security and Privacy	247
9.1	Security threats	248
9.2	Mitigation efforts to secure software	252
9.3	Privacy concerns	254
9.4	Data storage: cloud vs. device	254
9.5	Current trends and recommendations	255

10 Testing and Optimization	257
10.1 Testing mobile apps	257
10.2 Simulators	259
10.3 Caching and compression	264
10.4 Debugging	268
11 The Future of HTML5 and Mobile BI	273
11.1 Greater adoption of HTML5	273
11.2 Augmented reality	274
11.3 Mobile development takes precedence	276
12 Free Wire Frames, Mockups and Storyboards	277
12.1 Metro layout	277
12.2 Three columns with focus	278
12.3 Three columns with header and footer	279
12.4 Mobile navigation layout options	279
12.5 Two columns with left sidebar	280
13 OpenUI5 starter kit (download)	281

2 Mobility and BI

In 2014, the number of mobile devices exceeded the world's population. According to GSMA Intelligence, there were 7.2 billion mobile devices and roughly 7.19 billion people. Since then, the number of devices has grown significantly and stands closer to 8 billion, while population growth has reached approximately 7.6 billion. Also noteworthy in 2014 was that the number of mobile internet users overtook desktop users (see Figure 2.1). These are telltale signs for the future.

The year 2014 has been dubbed the “mobile revolution” and there is no indication of this losing momentum. Mobile ecommerce is growing exponentially and a study published in September 2014 on [blog.kissmetrics.com](https://blog.kissmetrics.com/surprising-mobile-ecommerce/) (<https://blog.kissmetrics.com/surprising-mobile-ecommerce/>), showed that 78 percent of business searches on a mobile phone resulted in a purchase. Tablets came in second with 64 percent and personal computers and laptops were third at 61 percent.

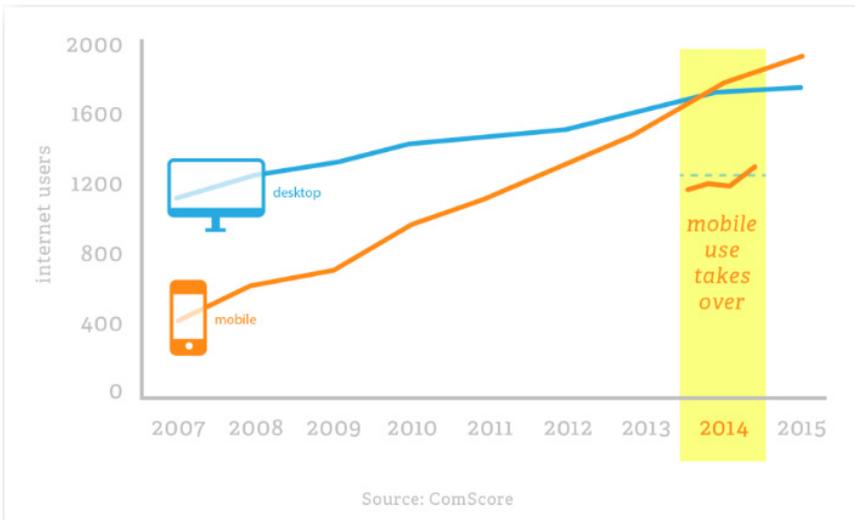

Figure 2.1: The growth of mobile and desktop internet users via ComScore

The most interesting statistic that has influenced the writing of this book is that customers prefer mobile websites to native apps. While it is documented that users spend up to 90 percent of their time in apps, 70 percent of users prefer to use mobile websites. Therefore, a good strategy would be to improve your mobile web experience as opposed to investing in more mobile apps; with HTML5, users have the best of both worlds with very little compromise.

2.1 The evolution of mobile devices

Historians note that Alexander Graham Bell invented the telephone in 1876 and held the first patent. Communication flourished via this new medium but it was confined by chords attached to non-portable devices. It took almost a century for the invention of the first mobile phone prototype by Motorola, and it was used to make a call in 1973.

In less than five decades, we have seen exponential growth and adoption of the mobile phone with incredible improvements and refinements. Today, we use the term “smartphones” to represent the new era of mobile devices. The IBM Simon was touted as the first smartphone back in 1993 because it had the capabilities of a phone, pager, fax machine and Personal Digital Assistant (PDA). Fast forward to 1999 and the Nokia 3210, which was one of the most popular mobile phones in history, with over 160 million handsets sold. Blackberry launched the 5810 in 2002, merging a phone with a data-only handset; and in 2007, Apple launched the first iPhone with quad-band GSM connectivity with GPRS and EDGE capabilities. A year later, Apple launched the iPhone 3G and since then, digital transformation growth has been exponential.

As mentioned at the beginning of this chapter, the gross number of mobile devices has exceeded the world’s population. However, the number of unique subscribers still stands at less than 5 billion, indicating that there is an average of 1.5 mobile devices per subscriber. According to GSMA Mobile Economy reporting (gsma.com), the penetration rate for unique subscribers in 2016 was 65 percent and is closer to 100 percent when we look at gross global connections. The number of unique mobile subscribers by 2020 is projected to be 5.7 billion, with a penetration rate of 73 percent.

Definitions

Feature Phone is a term to describe a class of mobile phone. The term is typically used to describe low-end mobile phones which are limited in capabilities in contrast to modern smartphones such as the iPhone. Feature phones typically provide voice calling and text messaging functionality in addition to basic multimedia and internet capabilities, and other services offered by the user's wireless service provider. *Source: Wikipedia*

A **Smartphone** is a mobile phone with an advanced mobile operating system which combines features of a personal computer operating system with other features useful for mobile or handheld use. Smartphones, which are usually pocket-sized, typically combine the features of a cell phone, with those of other popular digital mobile devices such as personal digital assistants (PDAs) (e.g. event calendar, media player, video games, GPS navigation, digital camera and digital video camera). *Source: Wikipedia*

The most interesting change is the rapid increase in smartphone adoption, coupled with data and broadband growth. In recent years, the sale of smartphones has outstripped feature phones, however global smartphone penetration stands at 40 percent compared to 60 percent for feature phones. While there are challenges associated with the increased use of mobile devices — such as battery life, security, and more alarming concerns linked to health, sleep, social aversion and driving — this has not slowed the adoption of mobile devices and there is no sign that it will be slowing down anytime soon.

Today, a mobile phone is not a rare and expensive commodity like it was forty years ago. The focus has now shifted to smartphone penetration versus feature phones. Smartphones are a marketer's dream because they can create more targeted campaigns and use location-based technologies via mobile apps or websites to drive traffic and increase sales. The global growth in internet penetration is helping to drive the shift to data and broadband, which in turn cannibalizes traditional voice services. But where there is a downturn, there is great opportunity.

2.2 The big data explosion

If the mobile revolution was prodigious, then the proliferation of big data is a modern phenomenon. Throughout history, libraries have been mankind's main source of organized collections of information and data that are easily accessible in a physical space. Items ranging from books, films, maps and newspapers to ancient artifacts such as tablets and manuscripts can all be found there; and today, even more content exists in modern libraries.

The need to collect, store and retrieve data is not a new sensation. However, advancements in technology have led to enormous growth in data, presenting new challenges and obstacles. In addition to the explanation of big data in Chapter 1, there are four distinct characteristics that help define it. Originally documented as the “3Vs” (volume, variety and velocity), recent trends have led to a fourth “V” due to growing concern regarding how we sift through mammoth volumes of data to find valuable information. Some persons also argue that a fifth “V” — veracity speaks to the quality and trustworthiness of big data. For this book, we will focus on the following four characteristics of big data:

- ▶ *variety* — new and different data streams that should be stored and processed for insight
- ▶ *volume* — the amount of data generated, which is currently outgrowing traditional storage capacity
- ▶ *velocity* — speed at which data is generated to facilitate real-time analytics and decision making
- ▶ *value* — identifying valuable data for extraction and analysis

The term big data emerged in the 1990's in scholarly articles and research papers. Big data was a 10-billion-dollar market in 2013, expected to increase to 53 billion in 2017 and projected to reach 76 billion in 2020. The most staggering numbers for big data are that 90 percent of the world's data was created in the last two years alone and 80 percent of the world's data is unstructured, unlike our earlier libraries and traditional databases.

There are 50 million tweets daily and almost 3 million emails sent every second; and these numbers continue to grow and intensify the complexi-

ty of big data. The widespread impact of big data is evidenced in job market demand and the high salaries for the elusive data scientist who possesses the blended skillsets of a PHD in Statistics and Computer Science coupled with an MBA. The reality is that we cannot matriculate enough students to meet this growing demand for analysts, data engineers and scientists. In addition, the major component lagging in this big data revolution is the technology to support growth and demand for data.

There has been significant progress in machine learning, NoSQL and artificial intelligence that has helped to ease some of the challenges with data storage, analysis and interpretation. However, we still have enormous challenges ahead because the growth of data's variety, volume and velocity has outstripped our ability to keep pace and compete effectively. In addition to complexity, security and privacy, there are major challenges associated with big data as organizations collect and analyze data on individuals, sometimes with no opt-in/opt-out options. Big data should be a focal point when you build a mobile application and while not all data stored may meet the characteristics listed previously, you should consider a big data strategy and how best to pursue the demand and growth of its swiftly changing requirements. Some experts argue that the benefits and opportunities provided by big data far outweigh the challenges, and while I do agree, the explosion is yet to be contained and meaningfully exploited.

2.2.1 Data architecture for mobile BI

Storing, processing and retrieving information are vital components of mobile BI. Traditional data warehouses storing historical data usually have a data lag when handling extract, transform and load (ETL) processes, sometimes 24 to 48 hours, which poses a challenge for real-time or near real-time analysis. Heavier reliance on automated processes can result in improvements in accessing information but this is more suited for structured data that has a constant standard format. We could also take a hybrid approach, where we look at information from our existing data warehouse compared to real-time transactions from our CRM or other transactional systems.

There are different technologies and architecture implementation options that can be used to provide a robust data layer for mobile BI, and com-
