2 Introduction to BI Edge 4.1

In this chapter, I will review the BI Edge Suite tools available from SAP. These tools are updated regularly. That is the primary reason why focusing on tools is not as effective as focusing the process.

2.1 BI Edge products and technologies

The BI Edge suite includes a full set of reporting tools that can be organized by function and complexity. For example, there are end user tools with lower levels of complexity, such as BI Launchpad and Xcelsius. The value of these tools is highly based on the infrastructure available to the project team. This infrastructure is designed with server-based tools that may be more complex, but are primarily designed for use by technical admins. For example, the Universe Design Tool creates the semantic layer and data connections in a hierarchy to publish relevant information in a business layer. The business layer data can then be consumed by BI Launchpad and Xcelsius applications. In the case study, I will configure a full information workflow example. Figure 2.1 highlights that there may be many tools and layers involved in generating a report that is embedded within a corporate reporting strategy. For some, this graphic may also highlight the jumble of tools and interface technologies within the solution architecture.

Figure 2.2 shows a partial view of the technologies and highlights the process from semantic to data and the business layer in red. You need to keep in mind that these three layers are at the core of the BI Edge concept; they are essentially the building blocks of the universe concept. Therefore, if you want to create a report in BI Edge, you very rarely just create a query and use the reporting tool to create a list and/or graphical visualization. The idea is that you can utilize a complex network of data sources, which you would connect on the lowest level called the semantic layer. By *semantic*, I mean the logical language established for reports, which will be represented by the data sources selected for the reporting infrastructure.

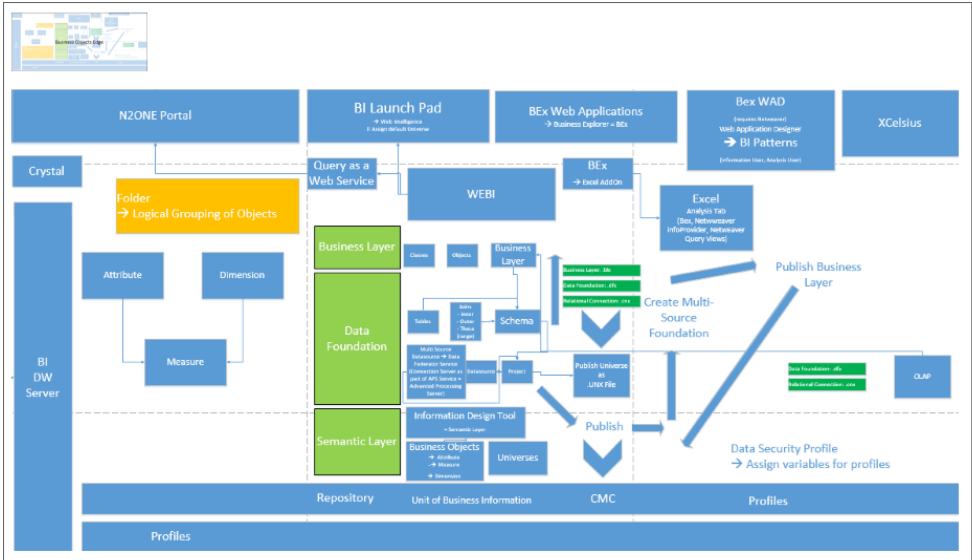

Figure 2.1: BI tools jungle

This selection will define the scope of data to deal with in reports. However, these data sources may have different representations of data and multiple areas of business focus. For example, there could be manufacturing and CRM data from various sources that may have unique column names for data. On the data foundation layer, this data is organized and prepared for business use. Then, in the third layer, the data is logically aligned with a business focus so that it can be easily understood by functional consultants for reporting.

While at first glance this may sound like a lot of overhead, the concept makes sense when you have complex data sources with multiple layers of privileges for user groups and departments. However, you are right that, for a simple report and ad hoc reporting, this concept may be perceived as a headache for a user who just needs to create a quick report in Excel. However, in the long run, the problems you face creating a mess of quick and dirty reports will be resolved with the organizational structure of the layered concept introduced with the universe.

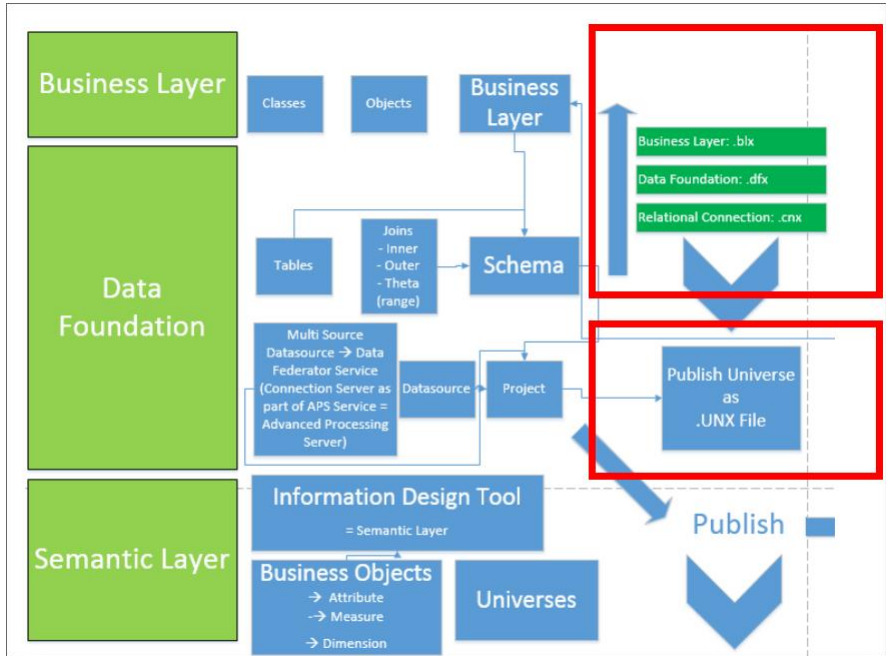

Figure 2.2: BI universe layers

In the following section, we will look at the BI Edge tools. In addition, we will review the tools that are already built in with SAP ECC. You will also learn how to connect them.

2.2 SAP ECC 6.0 reporting

BI Edge tools include the following applications:

- ▶ CMC Licensing
- ▶ Information Designer
- ▶ Universe Designer
- ▶ Crystal Reports

- ▶ WEBI
- ▶ Query as a Service
- ▶ BI LaunchPad
- ▶ Xcelsius

The *CMC – Central Management Console* is designed to manage the administrative overhead not covered by other tools. Essentially, the CMC must be used to manage the license for BI Edge, which will then determine the tools available to users. In BI Edge 4, a certain number of data services are included. However, the full feature set of data services is not included by default. The data services are a separate product that allow you to further integrate various data sources via service connectors and present the information by means of the semantic or data layer in the universe.

The *information designer* is the new version of the universe designer in BI Edge 4.x. It will replace the universe designer in future releases. Please note that, due to compatibility issues, you may have to use the universe designer for some older production systems. However, if you are deploying a new project, you can use the information designer.

One of the core reporting products in BI Edge is *Crystal Reports*. Crystal Reports can connect to data sources directly or also use BI Edge universes.

A *WEBI* is a Web Intelligence document that can be run in a browser. It usually integrates graphical representations of the data which are combined with a grid.

The *Query as a Service* tool is of particular interest, as using this technology efficiently is very powerful. Essentially, you can create a web service based on a query and then consume the web service in Xcelsius. I will look at this functionality further as part of the case study.

Xcelsius is an Excel-based add-on that includes various widgets to present data as a dashboard. For example, you can connect relevant data based on web services and drive graphics.

Figure 2.3 shows the BI Edge tools and also lists the InfoSet as part of the SAP ECC 6.0 built-in tools. As part of an accelerated BI implementation, a core aspect of the reporting strategy includes built-in reporting tools to help drive the BI Edge reports. The InfoSets will also be used during the case study. In fact, the first report created will use the InfoSet concept in SAP ECC 6.0.

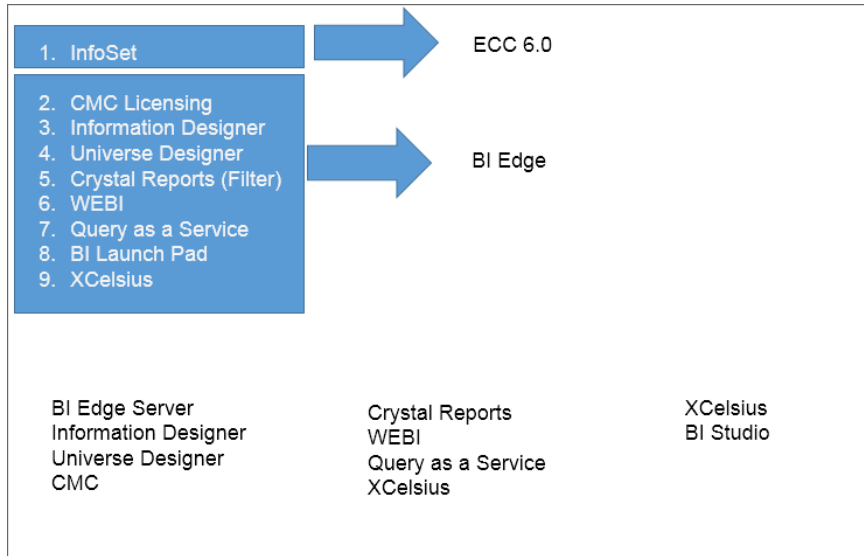

Figure 2.3: BI Edge tools

2.3 SAP BI Edge editions

The license code will determine the specific BI Edge product edition available to you. The license code is noted in the license management section of the CMC (see the details in Figure 2.4).
